

Information Sheet

Intellectual disability and bipolar disorder

Bipolar disorder (formerly known as manic-depressive illness) affects about one per cent of the general community. People who have bipolar disorder experience major changes in mood for no obvious reason. These repeated mood swings range from one extreme to another and the person is often completely well between the episodes of mania and depression.

The time between these different episodes can vary greatly from person to person, but usually episodes last days or weeks. It is not unusual for people with this disorder to become psychotic during depressive or manic episodes.

Recognising bipolar disorder

Changes in a person's emotional or behavioural state are classic signs/symptoms of bipolar disorder. There are a variety of symptoms that can occur in any number of combinations because bipolar disorder affects people in different ways.

Common symptoms for mania include:

- ▶ An elated, high, happy, excited, energetic or euphoric mood
- ▶ Having grandiose thoughts and plans which are an overestimation, especially in relation to the person's abilities
- ▶ Irritability which may include increased aggression or self injurious behaviour
- ▶ Needing less sleep than usual or going for long periods with very little sleep
- ▶ More talkative, rapid and insistent speech, talking loudly, seeking more attention, unable to attend to others speaking
- ▶ Rapid repetitive speech, jumping from one topic to another with little connection
- ▶ Inability to concentrate, skipping from activity to activity, highly distractible
- ▶ Lack of inhibitions, increase in sexual interests, intrusive, disregard for risks, spend money extravagantly
- ▶ High levels of activity and energy
- ▶ Lack of insight with the person being so convinced that their manic delusions are real that they do not realise they are unwell.

Most people with a bipolar disorder will also experience times of depression. Refer to the information sheet Intellectual disability and depression for more information.

Bipolar disorder and intellectual disability

People with intellectual disability can suffer from bipolar disorder. Research shows that the incidence is higher than the general population.

Like everyone with bipolar disorder, people with intellectual disability experience recurring episodes of depression and elation, both of which can vary from mild to severe. In between these episodes there are periods of normal mood. Additional signs that may present in a person with an intellectual disability can include:

- ▶ Sudden or gradual changes in usual behaviour
- ▶ Seeking reassurance
- ▶ Loss of skills
- ▶ Loss of bowel or bladder control
- ▶ Loss of ability to communicate
- ▶ Physical illness.

It is important to remember that many of the symptoms associated with a manic episode are often typical features of intellectual disability, for example, poor judgement, distractibility, excessive activity, aggression and so forth.

The key to determining whether a person is having a manic episode is to compare their current functioning with previous functioning.

What causes bipolar disorder?

The causes of this disorder are not fully understood, are different for each person and often there is combination of factors. However, the following are thought to be involved:

- ▶ Increased stress (for example, the departure of a favourite carer, changes in housing or work) and inadequate coping abilities can play a part in triggering the symptoms, but not always
- ▶ Genetic susceptibility: children of parents with bipolar mood disorder are at greater risk of developing the condition
- ▶ An imbalance of chemicals in the brain.

Getting help

The first step is awareness and the time to get professional help is when the behaviour changes. Speak to the person's GP, service coordinator, a mental health professional, psychiatrist, psychologist or counsellor .

For people with intellectual disability it may initially be useful to have a familiar person go to an appointment with them as family or carers will be able to provide some support and describe the changes they have noticed.

Data collection is a great help in the assessment, treatment and prevention of further episodes. This sets in place an objective behaviour observation system that can highlight patterns of behaviour changes over time.

Some treatment options involve a combination of support, psychological approaches and medication:

- ▶ **Cognitive behaviour therapy:** The person is helped to recognise patterns of thinking (cognition) and acting (behaviour) that are making them more likely to have problems or are keeping them from improving once they become unwell. Once these patterns are recognised, the person can make changes to replace these patterns with new ones that reduce symptoms and improve coping.

- ▶ **Counselling:** Assists people explore problems and resolve difficulties such as conflict and deal with grief or relationship issues. Counselling may involve the use of charts, pictures, photos, drawings and diaries to help describe feelings and worries and to try out alternative solutions.
- ▶ **Mood stabilising, anti psychotic and anti depressant medication:** Where possible, medication should be used in conjunction with other interventions.
- ▶ **Changing lifestyle and environmental factors** to reduce stress and ensure a stable, secure and safe environment.
- ▶ **Psycho-education:** Educating the person, family and support staff about bipolar disorder, its effects and how best to manage it.
